CIRCUIT DESCRIPTION

Frequency Configuration

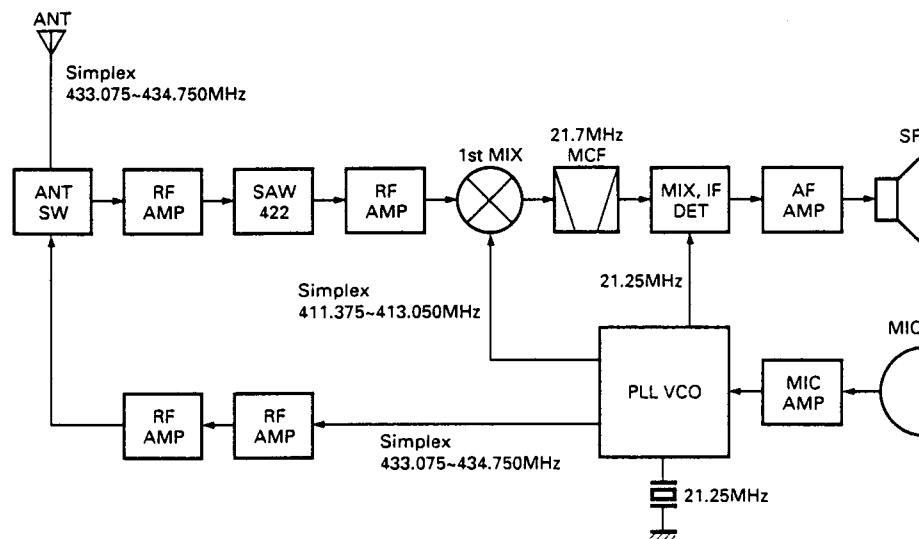

Fig. 1 Frequency configuration

Receiver System

■ Front End

The high-frequency signal from the antenna passes through a low-pass filter and a high-frequency switch diode (D8) (the receive side conducts in receive mode) which switches between transmission and reception, and goes to the high-frequency amplifier (Q13).

The signal output from Q13 enters the SAW filter (L18) to eliminate unwanted components. The resulting signal is amplified by high-frequency amplifier Q12 and goes to the first mixer (Q11).

■ First Mixer

The signal that reaches Q11 is mixed with the first local signal from the VCO to produce a first IF signal (21.7MHz).

(Receive frequency – First local frequency

$$= \text{First IF frequency} = 21.7\text{MHz}$$

The first IF signal passes through MCF: XF1 (monolithic crystal filter) to eliminate unwanted components.

The first IF signal is amplified by IF amplifier Q10 and goes to IF IC (IC2).

Reception method	Double super heterodyne	
	1st IF frequency	21.7MHz
2nd IF frequency		450kHz
Transmission method		VCO direct amplification
Modulation		Variable reactance phase modulation

Table 1

Item	Rating
Nominal center frequency (fo)	21.7MHz
Pass bandwidth	±7.5kHz or more at 3dB
Attenuation bandwidth	±25kHz or less at 18dB
Ripple	0.5dB or less
Insertion loss	1.5dB or less
Guaranteed attenuation	60dB or more within fo~fo-900kHz
Terminating impedance	1.5kΩ±5% / 2.5pF±0.2pF

Table 2 MCF (L71-0468-05) : TX-RX unit XF1

Item	Rating
6dB center frequency (fo)	Within 450kHz±1.5kHz
6dB bandwidth	±7.5kHz or more
50dB bandwidth	±15.0kHz or less
Ripple (Within 450±5kHz)	2dB or less
Guaranteed attenuation (±100kHz)	50dB or more
Insertion loss	4dB or less
I/O matching impedance	1.5kΩ

CIRCUIT DESCRIPTION

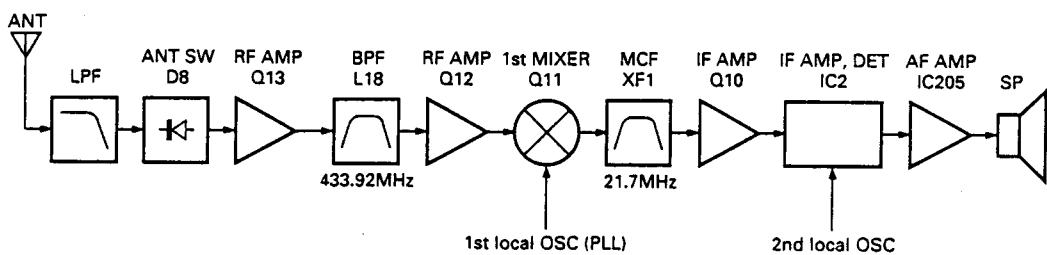

Fig. 2 Receiver section configuration

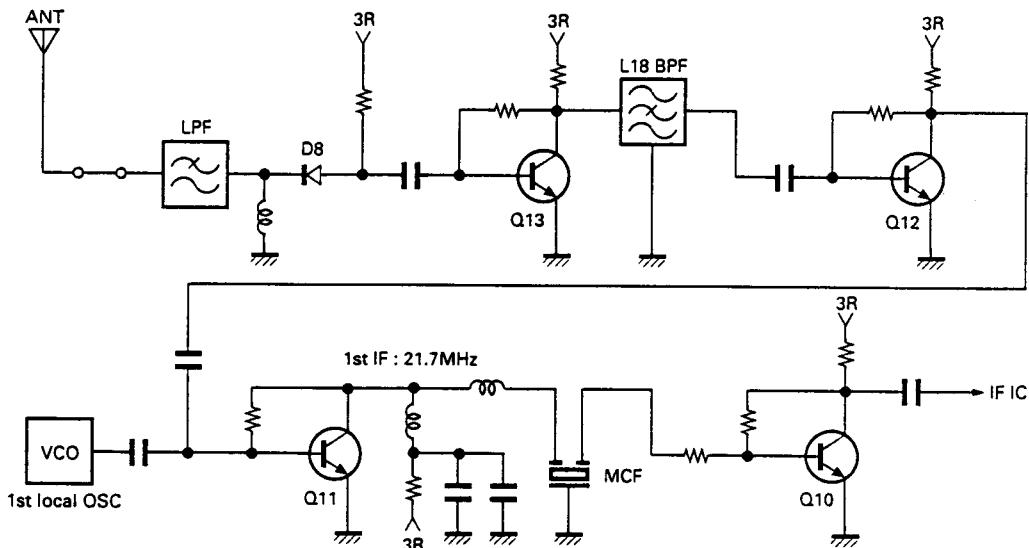

Fig. 3 Receiver circuit

■ IF Amplifier

The IF circuit consists of IC2. The IF IC contains local input, mixer, limiter amplifier, FM DET, and low-frequency amplifier.

The IF signal coming from the IF amplifier (Q10) goes to the IF IC mixer and is mixed with the second local signal (21.25MHz) to produce a second IF signal. (21.7MHz – 21.25MHz = 450kHz)

The second local signal is common to the PLL reference oscillation.

The second IF signal enters ceramic filter CF1 to eliminate unwanted signal components.

The second IF signal passing through the ceramic filter passes through the limiter amplifier consisting of six differential amplifiers and is detected.

The FM detection is quadrature detection. The phase of the output signal from the limiter amplifier is shifted by 90 degrees by a ceramic discriminator and compared with the original waveform to produce detection output.

UBZ-LF68

CIRCUIT DESCRIPTION

Squelch Circuit

A squelch circuit is provided to prevent no-signal noise or weak signals from outputting to a speaker during transmission.

The FM detection output is amplified by the operational amplifier in the base band IC (IC207), passes through a high-pass filter consisting of CR to remove noise components contained in the detection output, and converted to pulses by a comparator in the IC.

The output is input to the microcomputer. If a specified number of pulses is output (no-signal or weak signal), the audio amplifier IC power is turned off by the DC SW (Q210, Q202) to turn the output to the speaker off. To reduce noise output from the speaker when switching the audio amplifier off, the FET SW (Q203) directly connected to the speaker is turned off.

The squelch level is written into the EEPROM (IC203).

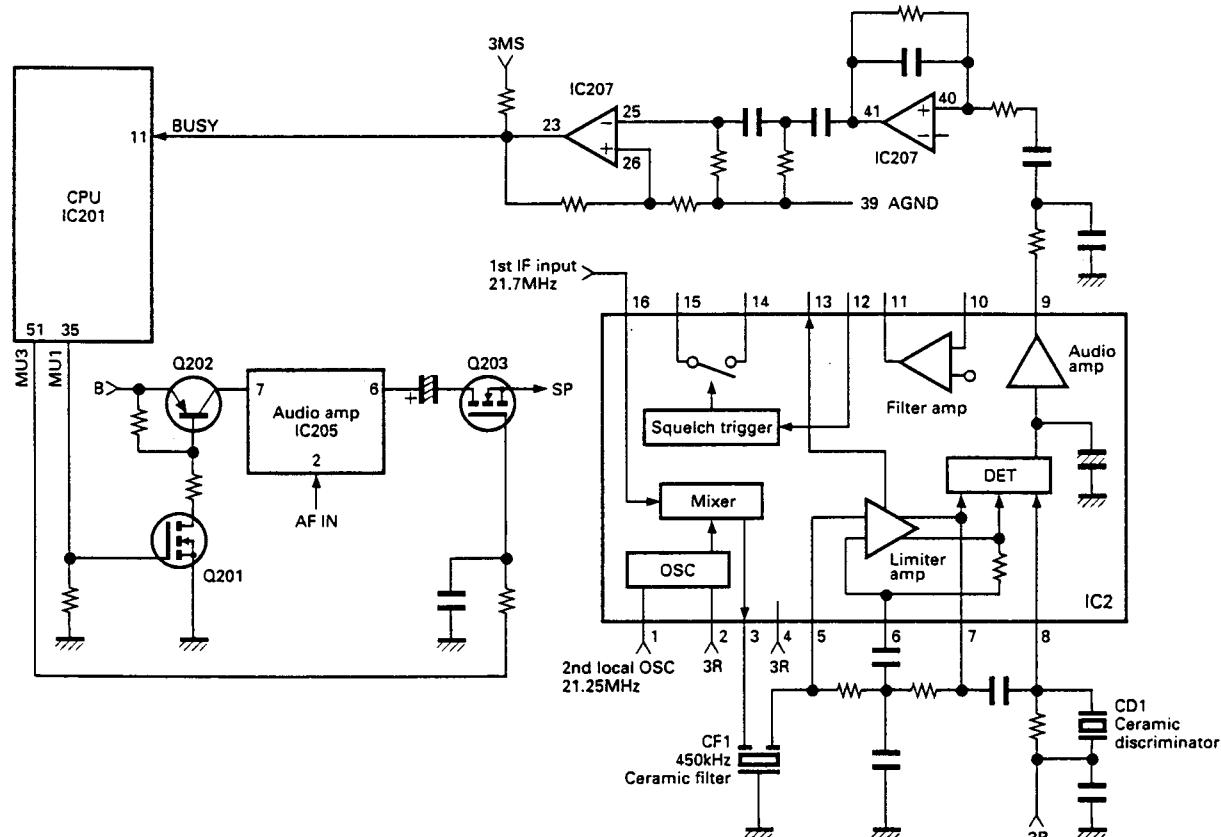

Fig. 4 IF and squelch circuits

AF Amplifier

The FM detection output passes through the amplifier contained in the base band IC (IC207), band-pass filter (300 to 3kHz), de-emphasis circuit, amplifier, and AF volume (VR201), and is amplified to the specified level by the AF amplifier (IC205).

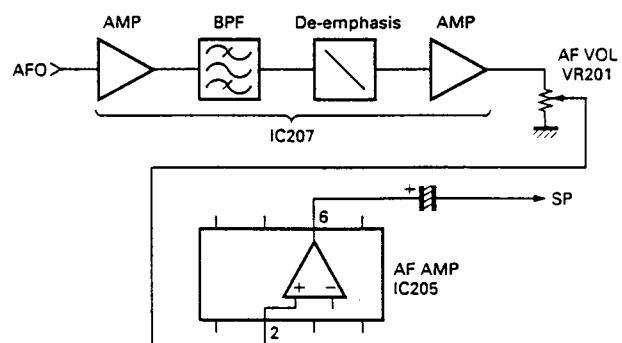

Fig. 5 AF circuit

CIRCUIT DESCRIPTION

Transmitter System

■ Microphone Amplifier Circuit

The audio signal from the microphone passes through the amplifier contained in the base band IC (IC207), 6dB/oct pre-emphasis circuit, band-pass filter (300 to 3kHz), amplifier, and limiter. The distortion components outside the audio band are eliminated by the splatter filter.

■ Modulation Circuit

The microphone amplifier output passes through VR206 for modulation adjustment and goes to the modulation input of the VCO circuit for variable reactance phase modulation.

■ Transmission Output Circuit

The VCO output is amplified by a high-frequency amplifier (Q5, Q6, Q7), passes through a high-frequency switch diode (D8) (which conducts in transmit mode), passes through a low-pass filter and goes to the antenna.

The transmission output is adjusted to 10mW at the transmission output pin by adjusting the operating voltage of Q7 by a semi-fixed volume (VR204).

Since the output from the transmission output circuit is kept at 3V, the transmission output does not fluctuate even when the power supply voltage changes.

■ Low-Pass Filter Circuit

A two-stage chebyshev type low-pass filter is located between the antenna and transmit/receive switching circuit. It removes harmonic components contained in the transmission output.

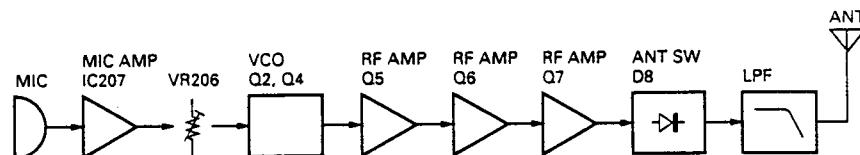

Fig. 6 Transmitter section configuration

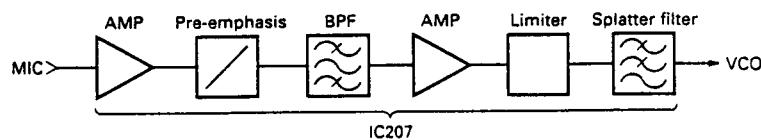

Fig. 7 Microphone amplifier circuit

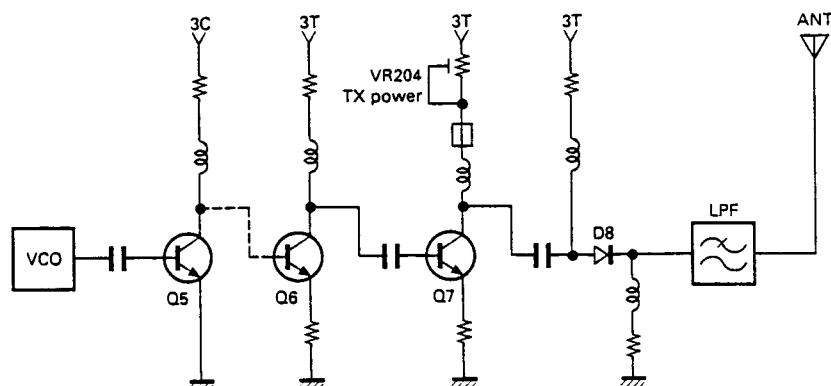

Fig. 8 Transmission output circuit

CIRCUIT DESCRIPTION

PLL System**■ VCO Circuit**

The VCO is housed in a shield case.

The VCO circuit consists of a transistor (Q2), a variable capacity diode (D1) for frequency control, a variable capacity diode (D3) for modulation, transmit/receive frequency shift diode (D2), control transistor (Q1), and oscillator buffer amplifier (Q4).

In receive mode, the shift signal T/R goes high, Q1 turns on, and the shift diode (D2) contacts. Q2 produces the first local frequency for reception.
(Receive channel frequency - 21.7MHz)

In transmit mode, the shift signal T/R goes low, Q1 turns off and D2 does not conduct. Q2 produces about 430MHz and the VCO frequency equals the transmit channel frequency.

The 3.0V circuit voltage is produced by ripple removing filter circuit Q3.

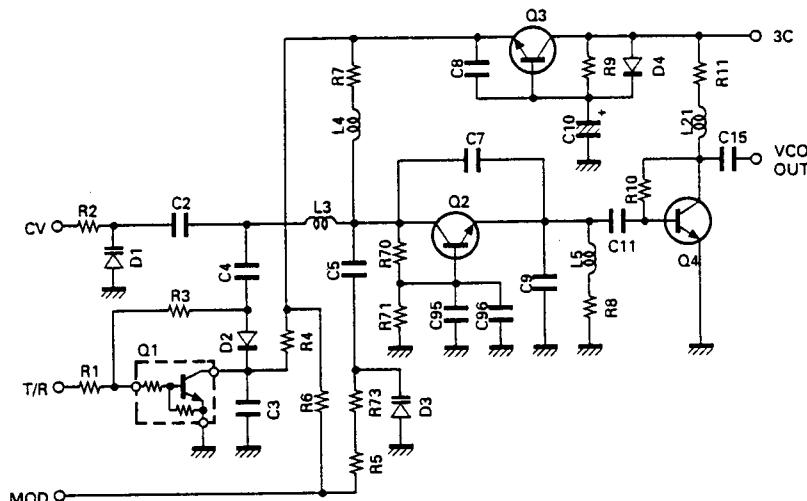

Fig. 9 VCO circuit

■ PLL Circuit

Frequency data is sent to the PLL IC (IC1) from the microcomputer as serial data when the power turns on, when the channel is changed, or when transmission begins. It sets the variable divider in the PLL IC.

The crystal oscillator X1 and the CMOS oscillator in the PLL IC produce a 21.25MHz reference frequency. It is divided to produce a 12.5kHz PLL comparison frequency.

The VCO input is divided by the divide ratio set by the divider in the PLL IC to generate 12.5kHz. It is compared with the reference comparison frequency by the phase comparator to detect a phase difference.

The charge pump circuit in the PLL IC converts it to a control voltage that can drive the VCO directly.

The control voltage passes through a loop filter which passes low frequency and is applied to the VCO control pin to control the oscillator frequency. The loop filter removes unwanted harmonics and noise contained in the output from the phase comparator and determines PLL response and synchronizing characteristics by the amplitude and phase characteristics (Fig. 10).

■ Unlock Detection Circuit

If the PLL cannot be synchronized for some reason or other when switching the channel or changing between transmission and reception, the PLL IC outputs a low unlock detection signal. This signal goes to the microcomputer to inhibit transmission when the PLL is unlocked.

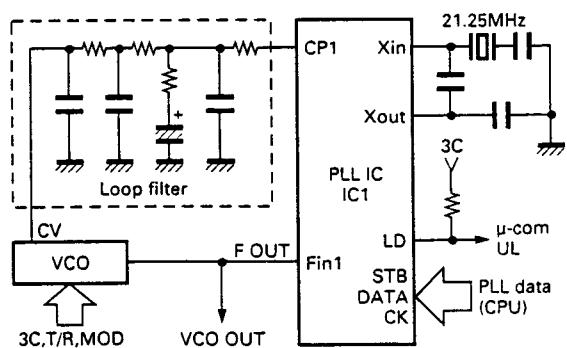

Fig. 10 PLL circuit

CIRCUIT DESCRIPTION

Control System

■ Reset Circuit

When a battery is inserted, the microcomputer (IC201) power supply provides the operating voltage after about 500 μ s. The voltage output IC (IC202) sets the reset pin to high to reset the microcomputer after about 500 μ s.

When the battery is removed, the voltage detection IC (IC206) detects the drop of the B power supply voltage, changes the detection output to low, and sends the signal to the VD pin of the microcomputer to stop its operation.

■ Battery Voltage Detection Circuit

The unit detects a low battery voltage and flashes the BATT indicator on the LCD. The battery voltage is divided and applied to the analog value input pin (BATT) of the microcomputer, and converted to a digital signal. It is compared with the reference voltage from the 3M power supply, and if it is lower than the preset value, the BATT indicator on the LCD flashes.

It is factory-set to flash when the battery terminal voltage falls to 3.5V.

■ Power Supply Circuit

The power supply voltage is maintained to 3.0V by the series regulator (IC204). It is used as microcomputer power 3M.

The transmission power 3T is supplied to the transmission output circuit when the microcomputer turns Q204 on only in transmit mode.

The reception power 3R is provided to the receive and IF circuits when the microcomputer turns Q205 (1/2) on only in receive mode.

The transmission/reception power 3C is supplied to the VCO and PLL circuits when the microcomputer turns Q205 (2/2) on in transmit and receive modes.

The power switch linking power supply 3MS is supplied to the base band IC (IC207) and divider (IC208) when the microcomputer turns Q209 on when the power switch is pressed.

If no signal is received for 10 seconds, the microcomputer enters the power save mode, and turns common power 3C and reception power 3R on for one cycle and off for three cycles according to the signals from the microcomputer to save the battery power. If the power save mode continues for two hours, the power switches off automatically and common power 3C, reception power 3R, and power switch linking power supply 3MS are turned off.

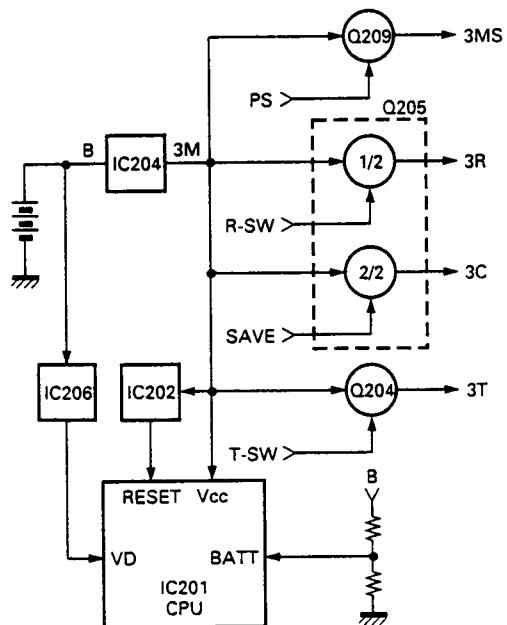

Fig. 11 Reset, battery voltage detection and power supply circuits

UBZ-LF68

CIRCUIT DESCRIPTION

■ Remote Control Circuit

The voltage at the CPU (IC201) REM (remote) pin is converted to a digital signal to carry out remote operation according to the voltage.

The REM pin is set to about 3.0V by R201. When the remote control microphone switch is pressed, the voltage divided by the resistor in series to the switch and R201 is generated to indicate which switch is pressed.

(*1): The voltage passes through R203 from the internal 3MS line (3.0V).

■ CTCSS

The tone frequency of the base band IC (IC207) is set by serial data from the CPU (IC201).

In receive mode, the FM demodulation output goes to the IC207 RXIN pin. If the tone frequency matches, the IC207 DET OUT pin goes low and the signal is applied to the microcomputer port. MU1 goes high and the AF amplifier power turns on. If the tone frequency does not match, no sound is output from the speaker.

In transmit mode, the tone set by the microcomputer is output from the IC207 TX TONE pin and the level is set by VR203. The resulting signal passes through the summing amplifier in IC207 to modulate the VCO.

EXPLODED VIEW

Parts with the exploded numbers larger than 700 are not supplied.

PACKING

UBZ-LF68

ADJUSTMENT

Required Test Equipment

1. DC V.M and Tester (DVM)

1) High input impedance

2. RF VTVM (RF V.M)

- 1) Input impedance : 1MΩ min., 2pF max.
- 2) Voltage range : F.S = 10mV to 300V
- 3) Frequency range : 500MHz or more

3. Frequency Counter (f. counter)

- 1) Input sensitivity : Approx. 500mV
- 2) Frequency range : 500MHz or more
- 3) Measurement stability : 0.2ppm or less

4. DC Power Supply

- 1) Voltage : 0V to 10V, variable
- 2) Current : Approx. 1A

5. Power Meter

- 1) Measurement range : Approx. 20mW
- 2) Input impedance : 50Ω
- 3) Frequency range : 500MHz or more

6. AF VTVM (AF V.M)

- 1) Input impedance : 1MΩ or more
- 2) Voltage range : F.S = 1mV to 3V
- 2) Frequency range : 50Hz to 10kHz

7. AF Generator (AG)

- 1) Output frequency : 100Hz to 10kHz
- 2) Output voltage : 0.5mV to 1V

8. Linear Detector or Deviation meter

- 1) Frequency range : 500MHz or more

9. Distortion Meter

- 1) Frequency range : 30Hz to 100kHz
- 2) Input level : 50mV to 10Vrms
- 3) Measurement stability : 3% or less at 1kHz

10. SSG

- 1) Frequency range : 30 to 500MHz
- 2) Modulation : FM
- 3) Output level : -133 to -13dBm

11. Oscilloscope

- 1) Measurement range : DC to 30MHz

12. Dummy Load

- 1) 8Ω, 1W

13. Spectrun analyzer

14. Tracking generator

Setting

1. Power voltage : DC 4.5V

Current protection : Approx. 300mA

2. Frequency (12.5kHz step)

Channel frequency (MHz)

3. CTCSS	2) TONE No. : 01 (67.0Hz) PTT : ON						Check LCD check	±0.35~0.7kHz 35-01 group on

Receiver Section

Item	Condition	Measurement			Adjustment			Specifications/Remarks
		Test-equipment	Unit	Terminal	Unit	Parts	Method	
1. Sensitivity	1) 34CH : 433.900MHz SSG frequency : 433.900MHz SSG output : -121dBm SSG MOD : 1kHz SSG DEV : 3.0kHz MONI SW ON : While pressing MODE and DOWN keys, POWER ON VOL : 0.63V/8Ω	SSG Distortion meter Oscilloscope AF V.M	RF Top panel	ANT (CN2) SP			Check	SINAD 12dB or more
2. Squelch	1) 34CH : 433.900MHz SSG output : -132dBm	SSG Oscilloscope AF V.M	RF	ANT (CN2)			Check	Squelch close
	2) SSG output : -126dBm							Squelch open
3. BATT	1) BATT terminal : DC3.45V±0.005V						LCD check	BATT mark blinking
	2) BATT terminal : DC3.55V±0.005V							BATT mark off

ADJUSTMENT

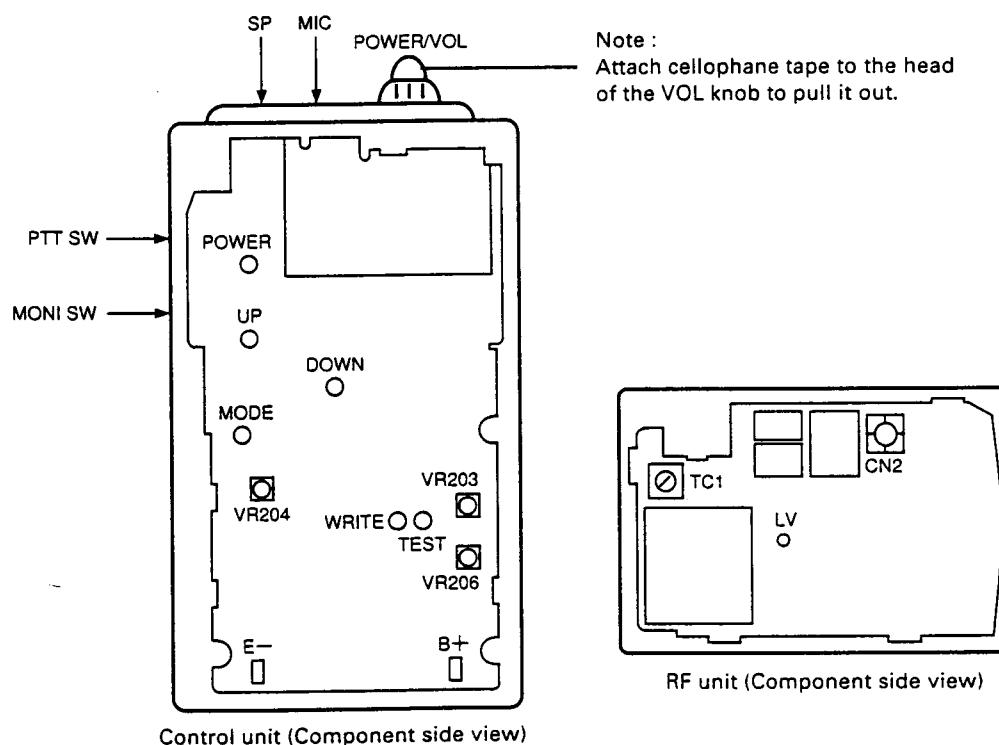

Writing the Battery Detection and Busy Detection (Squelch) Levels

The operation setting levels of these items are stored in IC203 (EEPROM) on the Control unit (X57-4872-71) (A/2) (factory set). If IC203 fails and is replaced, the levels must be adjusted as follows;

■ Writing battery detection

1. Set the power supply voltage to 3.5V.
2. While grounding the WRITE pattern, press the UP button.
3. When the data is written correctly, the "pururu" sound is output. (If it fails, the "pupupu" sound is output.)

Adjustment Points

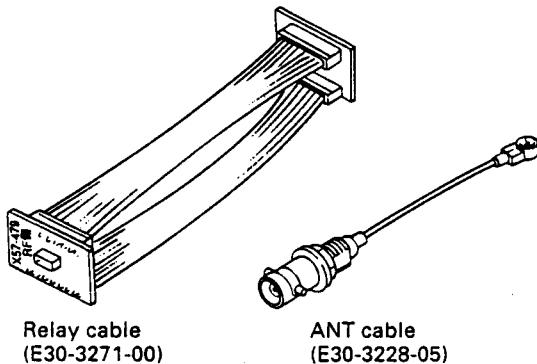

TC1 : Transmission frequency
 VR203 : TONE (CTCSS)
 VR204 : Power (Transmission power)
 VR206 : Deviation (Modulation)
 B, E : External power supply pin (Fasten it with an alligator clip.)
 WRITER : Writing

ADJUSTMENT / TERMINAL FUNCTION

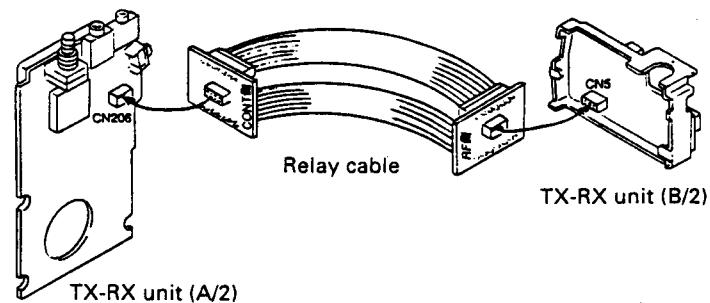

Jigs

Use jigs for repair or adjustment.

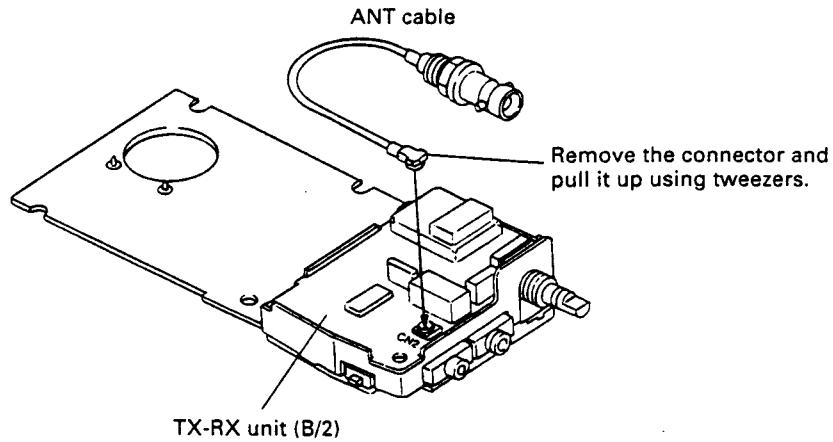

Connecting Jigs

- If the relay cable is inserted incorrectly, the unit does not work. Be sure to connect the cable correctly as shown in the illustration below.

- TX/RX

TERMINAL FUNCTION
